

CLOUD COMPUTING

Web Services, Service Oriented Architecture

PROF. SOUMYA K. GHOSH
DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING
IIT KHARAGPUR

What are "Web Services"?

"Software application identified by a URI, whose interfaces and bindings are capable of being defined, described, and discovered as XML artifacts" – W3C Web Services Architecture Requirements, Oct. 2002

"Programmable application logic accessible using Standard Internet Protocols..." – Microsoft

"An interface that describes a collection of operations that are network accessible through standardized XML messaging ..." – IBM

"Software components that can be spontaneously discovered, combined, and recombined to provide a solution to the user's problem/request ... " - SUN

History!

- Structured programming
- Object-oriented programming
- Distributed computing
- Electronic Data Interchange (EDI)
- World Wide Web
- Web Services

Distributed Computing

- When developers create substantial applications, often it is more efficient, or even necessary, for different task to be performed on different computers, called N-tier applications:
 - A 3-tier application might have a user interface on one computer, business-logic processing on a second and a database on a third all interacting as the application runs.
- For distributed applications to function correctly, application components, e.g. programming objects, executing on different computers throughout a network must be able to communicate.
 - E.g.: DCE, CORBA, DCOM, RMI etc.
- Interoperability:
 - Ability to communicate and share data with software from different vendors and platforms
 - Limited among conventional proprietary distributed computing technologies

Electronic Data Interchange (EDI)

- Computer-to-computer exchange of business data and documents between companies using standard formats recognized both nationally and internationally.
- The information used in EDI is organized according to a specified format set by both companies participating in the data exchange.
- Advantages:
 - Lower operating costs
 - Saves time and money
 - Less Errors => More Accuracy
 - No data entry, so less human error
 - Increased Productivity
 - More efficient personnel and faster throughput
 - Faster trading cycle
 - Streamlined processes for improved trading relationships

Web Services

- Take advantage of OOP by enabling developers to build applications from existing software components in a modular approach:
 - Transform a network (e.g. the Internet) into one library of programmatic components available to developers to have significant productivity gains.
- Improve distributed computing interoperability by using open (nonproprietary) standards that can enable (theoretically) any two software components to communicate:
 - Also they are easier to debug because they are text-based, rather than binary, communication protocols

Web Services (contd...)

- Provide capabilities similar to those of EDI (Electronic Data Interchange), but are simpler and less expensive to implement.
- Configured to work with EDI systems, allowing organisations to use the two technologies together or to phase out EDI while adopting Web services.
- Unlike WWW
 - Separates visual from non-visual components
 - Interactions may be either through the browser or through a desktop client (Java Swing, Python, Windows, etc.)

Web Services (contd...)

- Intended to solve *three* problems:
 - Interoperability:
 - Lack of interoperability standards in distributed object messaging
 - DCOM apps strictly bound to Windows Operating system
 - RMI bound to Java programming language
 - Firewall traversal:
 - CORBA and DCOM used non-standard ports
 - Web Services use HTTP; most firewalls allow access though port 80 (HTTP), leading to easier and dynamic collaboration
 - Complexity:
 - Web Services: developer-friendly service system
 - Use open, text-based standards, which allow components written in different languages and for different platforms to communicate
 - Implemented incrementally, rather than all at once which lessens the cost and reduces the organisational disruption from an abrupt switch in technologies

Web Service: Definition Revisited

- An application component that:
 - Communicates via open protocols (HTTP, SMTP, etc.)
 - Processes XML messages framed using SOAP
 - Describes its messages using XML Schema
 - Provides an endpoint description using WSDL
 - Can be discovered using UDDI

Example: Web based purchase

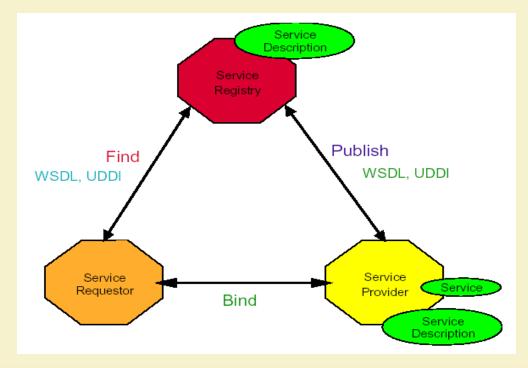

Service Oriented Architecture (SOA)

- IBM has created a model to show Web services interactions which is referred to as a Service-Oriented Architecture (SOA) consisting of relationships between three entities:
 - A service provider;
 - A service requestor;
 - A service broker
- IBM's SOA is a generic model describing service collaboration, not just specific to Web services.
 - See: http://www-106.ibm.com/developerworks/webservices/

Web Service Model

Web Service Model (contd...)

- Roles in Web Service architecture
 - Service provider
 - Owner of the service
 - Platform that hosts access to the service
 - Service requestor
 - Business that requires certain functions to be satisfied
 - Application looking for and invoking an interaction with a service
 - Service registry
 - Searchable registry of service descriptions where service providers publish their service descriptions

Web Service Model (contd...)

- Operations in a Web Service Architecture
 - Publish
 - Service descriptions need to be published in order for service requestor to find them
 - Find
 - Service requestor retrieves a service description directly or queries the service registry for the service required
 - Bind
 - Service requestor invokes or initiates an interaction with the service at runtime

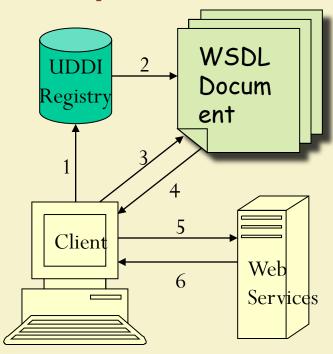

Web Service Components

- XML eXtensible Markup Language
 - A uniform data representation and exchange mechanism.
- SOAP Simple Object Access Protocol
 - A standard way for communication.
- WSDL Web Services Description Language
 - A standard meta language to described the services offered.
- **UDDI** Universal Description, Discovery and Integration specification
 - A mechanism to register and locate WS based application.

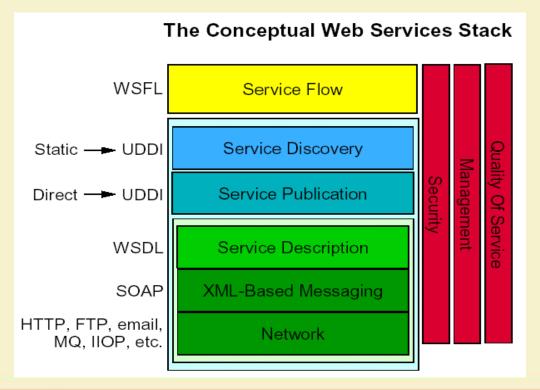

Steps of Operation

- 1. Client queries registry to locate service.
- Registry refers client to WSDL document.
- 3. Client accesses WSDL document.
- 4. WSDL provides data to interact with Web service.
- 5. Client sends SOAP-message request.
- 6. Web service returns SOAP-message response.

Web Service Stack

XML

- Developed from Standard Generalized Markup Method (SGML)
- Widely supported by W3C
- Essential characteristic is the separation of content from presentation
- Designed to describe data
- XML document can optionally reference a Document Type Definition (DTD), also called a Schema
 - XML parser checks syntax
 - If an XML document adheres to the structure of the schema it is valid

XML (contd...)

- XML tags are not predefined
 - You must define your own tags.
- Enables cross-platform data communication in Web Services

XML vs HTML

An HTML example:

```
<html>
<body>
  <h2>John Doe</h2>
  2 Backroads Lane<br>
      New York<br>
      045935435<br>
     john.doe@gmail.com<br>
      </body>
</html>
```

XML vs HTML (contd...)

This will be displayed as:

John Doe

2 Backroads Lane

New York

045935435

John.doe@gmail.com

- HTML specifies how the document is to be displayed, and not what information is contained in the document.
- Hard for machine to extract the embedded information. Relatively easy for human.

XML vs HTML (contd...)

Now look at the following:

- In this case:
 - The information contained is being marked, but not for displaying.
 - Readable by both human and machines.

SOAP

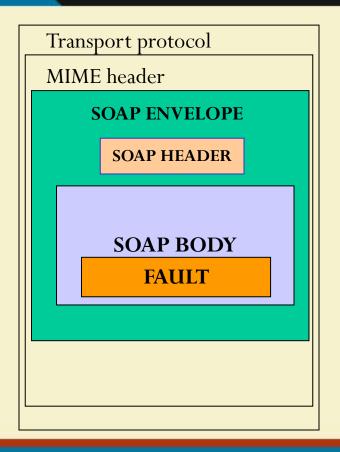

- Simple Object Access Protocol
- Format for sending messages over Internet between programs
- XML-based
- Platform and language independent
- Simple and extensible
- Uses mainly HTTP as a transport protocol
 - HTTP message contains a SOAP message as its payload section
- Stateless, one-way
 - But applications can create more complex interaction patterns

SOAP Building Blocks

- Envelope (required) identifies XML document as SOAP message
- Header (optional) contains header information
- Body (required) –call and response information
- Fault (optional) errors that occurred while processing message

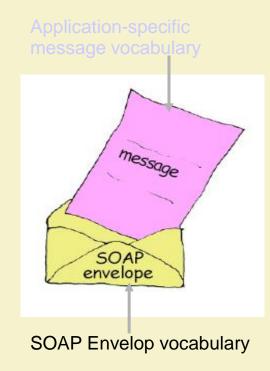

SOAP Message Structure

- Request and Response messages
 - Request invokes a method on a remote object
 - Response returns result of running the method
- SOAP specification defines an "envelop"
 - "envelop" wraps the message itself
 - Message is a different vocabulary
 - Namespace prefix is used to distinguish the two parts

SOAP Request

```
POST /InStock HTTP/1.1
Host: www.stock.org
Content-Type: application/soap+xml; charset=utf-8 Content-Length: 150
<?xml version="1.0"?>
<soap:Envelope
xmlns:soap="http://www.w3.org/2001/12/soap-envelope"
soap:encodingStyle=http://www.w3.org/2001/12/soap-encoding">
  <soap:Body xmlns:m="http://www.stock.org/stock">
        <m:GetStockPrice>
           <m:StockName>IBM</m:StockName>
       </m:GetStockPrice>
  </soap:Body>
</soap:Envelope>
```

SOAP Response

```
HTTP/1.1 200 OK
Content-Type: application/soap; charset=utf-8
Content-Length: 126
<?xml version="1.0"?>
<soap:Envelope xmlns:soap="http://www.w3.org/2001/12/soap-envelope"</pre>
soap:encodingStyle="http://www.w3.org/2001/12/soap-encoding">
   <soap:Body xmlns:m="http://www.stock.org/stock">
        <m:GetStockPriceResponse>
                 <m:Price>34.5</m:Price>
        </m:GetStockPriceResponse>
    </soap:Body>
</soap:Envelope>
```

Why SOAP?

- Other distributed technologies failed on the Internet
 - Unix RPC requires binary-compatible Unix implementations at each endpoint
 - CORBA requires compatible ORBs
 - RMI requires Java at each endpoint
 - DCOM requires Windows at each endpoint
- SOAP is the platform-neutral choice
 - Simply an XML wire format
 - Places no restrictions on the endpoint implementation technology choices

SOAP Characteristics

- SOAP has three major characteristics:
 - Extensibility security and WS-routing are among the extensions under development.
 - Neutrality SOAP can be used over any transport protocol such as HTTP, SMTP or even TCP.
 - Independent SOAP allows for any programming model.

SOAP Usage Models

- RPC-like message exchange
 - Request message bundles up method name and parameters
 - Response message contains method return values
 - However, it isn't required by SOAP
- SOAP specification allows any kind of body content
 - Can be XML documents of any type
 - Example:
 - Send a purchase order document to the inbox of B2B partner
 - Expect to receive shipping and exceptions report as response

SOAP Security

- SOAP uses HTTP as a transport protocol and hence can use HTTP security mainly HTTP over SSL.
- But, since SOAP can run over a number of application protocols (such as SMTP) security had to be considered.
- The WS-Security specification defines a complete encryption system.

WSDL - Web Service Definition Language

- WSDL: XML vocabulary standard for describing Web services and their capabilities
- Contract between the XML Web service and the client
- Specifies what a request message must contain and what the response message will look like in unambiguous notation
- Defines where the service is available and what communications protocol is used to talk to the service.

WSDL Document Structure

- A WSDL document is just a simple XML document.
- It defines a web service using these major elements:
 - port type The operations performed by the web service.
 - message The messages used by the web service.
 - types The data types used by the web service.
 - **binding** The communication protocols used by the web service.

A Sample WSDL

```
<message name="getTermRequest">
 <part name="term" type="xs:string"/>
</message>
<message name="getTermResponse">
 <part name="value" type="xs:string"/>
</message>
<portType name="glossaryTerms">
 <operation name="getTerm">
   <input message="getTermRequest"/>
   <output message="getTermResponse"/>
 </operation>
</portType>
```

Binding to SOAP

```
<message name="getTermRequest">
 <part name="term" type="xs:string"/>
</message>
<message name="getTermResponse">
 <part name="value" type="xs:string"/>
</message>
<portType name="glossaryTerms">
 <operation name="getTerm">
   <input message="getTermRequest"/>
   <output message="getTermResponse"/>
 </portType>
<br/><br/>dinding type="glossaryTerms" name="b1">
<soap:binding style="document"</pre>
transport="http://schemas.xmlsoap.org/soap/http"/>
 <operation>
  <soap:operation
  soapAction="http://example.com/getTerm"/>
  <input>
   <soap:body use="literal"/>
  </input>
  <output>
   <soap:body use="literal"/>
  </output>
 </binding>
```

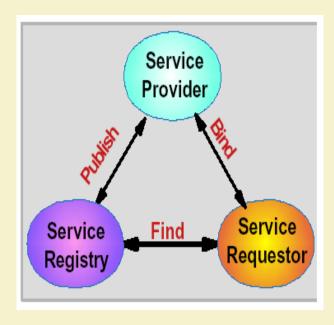

UDDI - Universal Description, Discovery, and Integration

- A framework to define XML-based registries
- Registries are repositories that contain documents that describe business data and also provide search capabilities and programmatic access to remote applications
- Businesses can publish information about themselves and the services they offer
- Can be interrogated by SOAP messages and provides access to WSDL documents describing web services in its directory

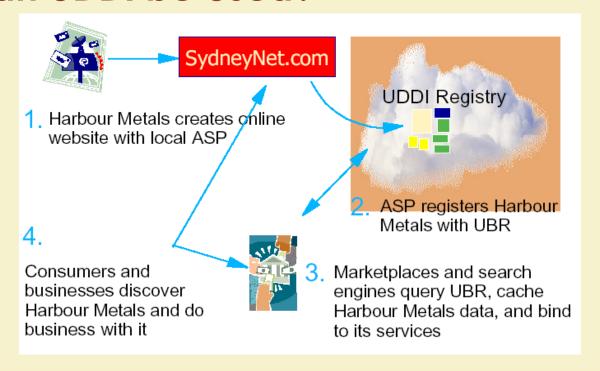

UDDI Roles and Operations

- Service Registry
 - Provides support for publishing and locating services
 - Like telephone yellow pages
- Service Provider
 - Provides e-business services
 - Publishes these services through a registry
- Service requestor
 - •Finds required services via the Service Broker
 - •Binds to services via Service Provider

How can UDDI be Used?

UDDI Benefits

- Making it possible to discover the right business from the millions currently online
- Defining how to enable commerce once the preferred business is discovered
- Reaching new customers and increasing access to current customers
- Expanding offerings and extending market reach

Web Services Security Architecture

WS-Secure Conversation WS-Federation WS-Authorization WS-Policy WS-Trust WS-Privacy WS-Security SOAP

Thank You!
